# Finnish Registry for Kidney Diseases – Report 2015

## Content

Board of the Finnish Registry for Kidney Diseases.....	4
Finnish Registry for Kidney Diseases 2015.....	5
Summary of Report.....	6

### Demography

The Finnish population (as thousands of inhabitants) and its distribution in healthcare districts, 2005–2015 .....	7
Healthcare districts and regions in Finland, 2015.....	7
The Finnish population (as thousands of inhabitants) according to region, age group, and sex, 2005–2015 .....	8

### Incidence of RRT

Number of new RRT patients and incidence of RRT by healthcare district and region, 2005–2015 .....	9
Number of new RRT patients by age group in healthcare districts and regions, 2011–2015 .....	10
Number of new RRT patients by age group and sex, 2005–2015.....	11
Incidence of RRT according to diagnosis, 1965–2015 .....	12
Number of RRT patients at 90 days from start of RRT according to type of treatment in healthcare districts and regions, 2011–2015 .....	13
Distribution of treatment modalities at 90 days from start of RRT in patients older than 20 years, 2005–2015 .....	14
Proportion of home dialysis and kidney transplantation patients of all RRT patients older than 20 years at 90 days from start of RRT, 2011–2015 .....	14
International comparison of incidence of RRT in 2014.....	15

### Prevalence of RRT

Patients on RRT at end of year according to healthcare district and region, 2005–2015 .....	16
Patients on RRT according to age group and sex, 2005–2015.....	17
Standardized prevalence of RRT in regions, 2005–2015.....	17
Prevalence of RRT on 31 December 2015.....	18
Prevalence of RRT at end of year according to type of treatment, 1965–2015 .....	19
Prevalence of dialysis and kidney transplantation in healthcare districts and regions, 2005–2015 .....	20
Number of RRT patients at end of year according to type of treatment in healthcare districts and regions, 2015 .....	21
International comparison of prevalence of RRT on 31 December 2014.....	22
Number of patient-years of all RRT patients according to diagnosis and type of treatment, 2005–2015 .....	23
Net changes in type of treatment, 2015 .....	24

### RRT patients' mortality

Mortality of RRT patients by region, 2005–2015 .....	25
Standardized mortality of RRT patients by region, 2005–2015.....	25
Standardized mortality of RRT patients by region (patients who died within 90 days of start of RRT excluded), 2005–2015 .....	25

### Analysis of quality of care

Number of RRT patients older than 20 years in hospitals, 2015 .....	26
Nephrological follow-up before start of RRT in patients older than 20 years according to year of start of RRT, 2011–2015 .....	27

Proportion of patients older than 20 years with nephrological follow-up shorter than 7 days before start of RRT, 2011–2015 .....	27
Nephrological follow-up before start of RRT of patients older than 20 years according to age group and sex, 2011–2015 .....	28
<i>All dialysis patients</i>	
Hemoglobin distribution of dialysis patients older than 20 years at end of year, 2005–2015 .....	29
Proportion of dialysis patients older than 20 years with hemoglobin concentration $\geq 100$ g/l in healthcare districts and regions, 2015 .....	29
Distribution of serum phosphorus among dialysis patients older than 20 years at end of year, 2005–2015 .....	30
Proportion of dialysis patients older than 20 years with serum phosphorus $< 1.8$ mmol/l in healthcare districts and regions, 2015 .....	30
<i>Hemodialysis patients</i>	
Vascular access of new hemodialysis patients older than 20 years by region, 2014–2015 .....	31
Vascular access of hemodialysis patients older than 20 years at end of year, 2005–2015 .....	32
Proportion of hemodialysis patients older than 20 years with a fistula or graft in healthcare districts and regions, 2015 .....	32
Sufficiency of dialysis time among hemodialysis patients aged 20–74 years, 2005–2015 .....	33
Proportion of hemodialysis patients aged 20–74 years with sufficient dialysis time in healthcare districts and regions, 2015 .....	33
Distribution of predialytic blood pressure among hemodialysis patients older than 20 years, 2005–2015 .....	34
Proportion of hemodialysis patients older than 20 years with predialytic blood pressure $< 140/90$ mmHg in healthcare districts and regions, 2015 .....	34
<i>Peritoneal dialysis patients</i>	
Number of PD peritonitis patients older than 20 years according to annual number of episodes peritonitis, 2005–2015 .....	35
Incidence density of peritonitis among PD patients older than 20 years in regions, 2005–2015 .....	35
Incidence density of peritonitis among PD patients according to age group and sex, 2011–2015 .....	36
Incidence density of peritonitis among PD patients older than 20 years according to age group and diabetes status, 2011–2015 .....	36
<i>Kidney transplantation</i>	
Time to waitlisting for kidney transplantation of new RRT patients older than 20 years, 2005–2015 .....	37
Time to waitlisting for kidney transplantation by age group of new RRT patients older than 20 years, 2005–2015 .....	37
Proportion of new RRT patients waitlisted for kidney transplantation within 91 days from start of RRT in healthcare districts, 2011–2015 .....	38
Proportion of new RRT patients waitlisted for kidney transplantation within 181 days from start of RRT in healthcare districts, 2011–2015 .....	38
Number of kidney transplantations and incidence density of kidney transplantation among dialysis patients, 2005–2015 .....	39
Standardized incidence density of kidney transplantation among dialysis patients, 2005–2015 .....	39
Incidence density of kidney transplantation among dialysis patients according to age group and sex, 2005–2015 .....	40
Incidence density of kidney transplantation among dialysis patients according to age group and time period, 2005–2015 .....	40
Distribution of blood pressure of kidney transplantation patients older than 20 years, 2005–2015 .....	41
Proportion of kidney transplantation patients older than 20 years with blood pressure $< 130/80$ mmHg in healthcare districts and regions, 2015 .....	41
Distribution of serum LDL cholesterol among kidney transplantation patients older than 20 years, 2005–2015 .....	42
Proportion of kidney transplantation patients older than 20 years with serum LDL cholesterol $< 2.6$ mmol/l in healthcare districts and regions, 2015 .....	42
Index 2003–2015 .....	43

## *Board of the Finnish Registry for Kidney Diseases*

Anniina Pylsy

### *The Registry has a new chairman*

After having served as the chair of the Board since the Finnish Registry for Kidney Diseases was founded in the late 1980s, Professor Carola Grönhagen-Riska resigned from her position in 2016. Under her leadership, the Registry developed into what it is today, an established national renal registry highly regarded both in Finland and internationally.

In its meeting in December 2016, the Board of the Finnish Registry for Kidney Diseases elected Professor Per-Henrik Groop as its new chairman. He serves as a Professor of Internal Medicine at the University of Helsinki and Chief Physician at the Department of Nephrology, Helsinki University Central Hospital.

## *Finnish Registry for Kidney Diseases 2015*

The Finnish Registry for Kidney Diseases contains data on dialysis and kidney transplantation patients in Finland since 1964. Since the beginning of the 1990s, the registry has published an annual report with information on the number of patients currently on renal replacement therapy (RRT, i.e. dialysis or kidney transplantation) as well as those entering RRT. Information on quality of treatment is presented for healthcare districts and regions. The report gives updates on causes of end-stage renal disease, e.g. specifying the renal diseases that are becoming more common, which is important information for disease prevention. Every few years (most recently Report 2014), projections on future numbers of RRT patients are also presented, which assists in planning of healthcare resources.

The data provided by the Finnish Registry for Kidney Diseases enable international comparisons of, for instance, incidence of RRT and survival of RRT patients. In recent years, the registry data have been used extensively for research, and dozens of articles on such topics as factors affecting patients' survival on RRT have been published in international medical journals.

The basis for the Finnish Registry for Kidney Diseases is cooperation with the staff of nephrology units, who send data to the registry when a patient enters RRT and thereafter at the end of each year. We thank the nephrology units for excellent data reporting; for many of the variables, the national coverage is more than 99%!

The Finnish Registry for Kidney Diseases is a national healthcare registry maintained by the Finnish Kidney and Liver Association. Since the beginning of the 1990s, the registry has been financed by the Finnish government, first through the Slot Machine

Association and since 2010 by the National Institute of Health and Welfare (THL). In 2016, our registry also received support from the Liv och Hälsa Association. In 2016 THL has decided to gradually withdraw its support. The total annual budget of the registry has for many years been 80 000 euros. In 2017, THL will pay half of that, in 2018 one-fourth, and in 2019 the funding will cease.

Because of the funding problem, we have asked the healthcare districts for support, and 18 of 21 districts have agreed to pay 10 euros per RRT patient for the year 2017. Some of the districts have already notified that this support will not continue beyond 2017, as they in principle will not take on the financial responsibility for healthcare registries from the government. Thus, the funding for 2018 is uncertain. We are trying to find a new source of funding and this work will continue in 2017. The treatment of all dialysis and kidney transplantation patients in Finland is estimated to cost more than 100 million euros. The budget of the Finnish Registry for Kidney Diseases is less than 0.1% of that and corresponds to the annual costs of treating 1–2 dialysis patients. We hope that the Finnish Registry for Kidney Diseases will receive funding and be able to continue its activities.

Chairman of the Board

## Summary of Report

### Finnish population (pages 7–8)

The Finnish population increased by 4.4% in 2005–2015, but the trend is not uniform over the entire country; in 11 healthcare districts, the population decreased. The Finnish population has in ten years become older and the proportion of inhabitants older than 65 years has increased from 16% to 20%. According to Statistics Finland, the population will continue to become older over the next few years.

### Incidence of RRT, number of patients entering RRT (pages 9–15)

In 2015, the incidence of RRT was 95 new RRT patients per million inhabitants, which was 11% larger than the year before. In an international comparison, the incidence in Finland is low. In the age group 75 years and older, the incidence is especially low, 190 per million age-related inhabitants, whereas it is 350–500 per million age-related inhabitants in the other Nordic countries. The most frequent kidney disease diagnoses of patients who entered RRT are type 2 diabetes, type 1 diabetes, glomerulonephritis, and polycystic degeneration. Three months after start of RRT, 30% of patients were on home dialysis (peritoneal dialysis or home hemodialysis), but the proportion varied significantly between healthcare districts. Three months after start of RRT, 2% had received a kidney transplant, which is a substantially smaller proportion than in the other Nordic countries (9–15%).

### Prevalence of RRT, number of patients at end of year (pages 16–24)

At end of 2015, there were 1836 dialysis patients and 2833 kidney transplantation patients in Finland. The prevalence of RRT was 851 patients per million inhabitants, which is lower than in most other European countries. In healthcare districts, the prevalence of RRT varied between 654 and 1 174 patients per million inhabitants. During the past ten years the number of dialysis patients had increased by 18% and the number of kidney transplantation patients by 29%. The most frequent kidney disease diagnosis of kidney transplantation patients was glomerulonephritis (22% of patients), of hemodialysis patients it was type 2 diabetes (20%), and of peritoneal dialysis patients it was type 1 diabetes (21%).

### RRT patients' mortality (page 25)

In 2011–2015, the mortality of RRT patients was 87 deaths per 1000 patient-years. Mortality was slightly higher in the northern and western regions than elsewhere. During the past ten years mortality has decreased in all regions.

### Quality of care (pages 26–42)

This is the fourth year that analyses of quality of care are presented in the Report. The results are given according to healthcare district and region, and the most essential analyses are repeated every year. New analyses in this Report are length of nephrological follow-up before start of RRT, vascular access at start of hemodialysis, peritoneal dialysis patients' peritonitis episodes, and dialysis patients' incidence density of kidney transplantation.

In 2011–2015, 13% of patients older than 20 years entering RRT had been followed up by a nephrologist for less than seven days before start of RRT. Of patients older than 20 years who started hemodialysis, 46% had an arteriovenous fistula or graft, but 31% had a temporary non-cuffed central venous catheter, which is recommended only when dialysis is started acutely.

In 2011–2015, peritoneal dialysis patients' incidence density of peritonitis was 420 per 1000 patient-years. Risk of peritonitis had decreased by 15% since 2005–2010. Males, diabetes patients, and patients older than 75 years had an increased risk of peritonitis.

Of dialysis patients, 69% reached the target of serum phosphorus (<1.8 mmol/l), but the proportion of those reaching the target varied significantly between healthcare districts and regions.

In the entire country, 7% of patients had been wait-listed for kidney transplantation within 90 days since start of RRT in 2011–2015. Incidence density of kidney transplantation among dialysis patients was higher in 2014–2015 than in earlier years. The frequency of kidney transplantation was similar in all regions. Of kidney transplantation patients, 64% reached the treatment target of LDL cholesterol (serum concentration <2.6 mmol/l), but the proportion reaching the target varied in the range of 22–76% in healthcare districts.

Figure 1. Healthcare districts and regions in Finland  
Finnish Registry for Kidney Diseases 2015

On 31 December 2015, the population of Finland was 5.487 million (Table 1, Source: Statistics Finland). During the past ten years the population of the country has increased by 4.4%, with the fastest increase occurring in the southern region. The population in the eastern region has decreased. Of the healthcare districts, the population has increased most (more than 5%) in Helsinki-Uusimaa, Åland, Pirkanmaa, Pohjois-Pohjanmaa, and Vaasa. In the healthcare districts of Itä-Savo, Kainuu, Etelä-Savo, and Länsi-Pohja, the population has decreased especially rapidly.

The numbers in Figure 1 refer to the healthcare districts listed in Table 1. In this report, “region” refers to a university hospital region.

Table 2 shows the age and sex distribution of the Finnish population at the end of 2005 and 2015. At the end of 2015, 20% of the population was older than 65 years. In 2005, this proportion was 16%. In the southern region, the proportion of inhabitants older than 65 years was the smallest, 18%, whereas in the other regions it was 20–23%. The proportion of inhabitants aged 20–64 years was largest in the southern region, 60%, while it was 56% in all other regions. In the northern region, the proportion of inhabitants younger than

20 years was the largest, 24%.

The age of the Finnish population has increased during the past ten years. The proportion of inhabitants older than 75 years has increased from 7% to 9%, and the proportion of 65–74-year-olds from 9% to 12%. The proportion of inhabitants older than 65 years has increased equally in all regions. The proportion of 20–64-year-olds has decreased from 61% to 58%.

Table 3 shows the number of new RRT patients and the incidence of RRT according to healthcare district and region. In the entire country, the incidence of RRT in 2015 was 95 new RRT patients per million inhabitants, which was larger than in 2014 and also larger than the average incidence in 2011–2015. However, the incidence in 2015 was somewhat smaller than in 2005. In 2011–2015, the average incidence was highest in the western region and lowest in the south-

ern region. In Table 3 and in the entire report, results are presented according to the region as of 1 January 2013 (when Vaasa healthcare district became part of the southwestern region instead of the western region).

In the healthcare districts, the average incidence in 2011–2015 was lowest in Pohjois-Pohjanmaa and Lapland (<75 new RRT patients per million inhabitants) and highest in Kanta-Häme and Itä-Savo (>125/million inhabitants).

Table 4. Number of new RRT patients by age group in healthcare districts and regions  
Finnish Registry for Kidney Diseases 2011–2015

\*Average annual incidence of RRT in subgroup

Table 4 presents the average annual number of new RRT patients and incidence of RRT in 2011–2015 according to healthcare district, region, and age group. The incidence was highest among 65–74-year-olds.

In the age group of 75 years and older, the incidence was 190 new RRT patients per million age-related inhabitants and varied in healthcare districts in the range of 0–366 and in regions in the range of 123–238. The incidence of RRT among inhabitants older than 75 years was considerably smaller in Finland than in the other Nordic countries, which ranged between 353 and 495 new RRT patients per million age-related inhabitants in 2014 (Annual Report 2014, <http://www.era-edta-reg.org>).

Table 5. Number of new RRT patients by age group and sex

Table 5 shows the number of new RRT patients and the incidence of RRT according to age group and sex in 2005–2015. The incidence of RRT was more than twice as high in men as in women, and the difference was even larger in the older age groups. In those 75 years and older, the incidence in 2015 was 35% lower than in 2005. In the other age groups, the incidence has remained virtually unchanged in the ten-year period.

Figure 2. Incidence of RRT according to diagnosis  
Finnish Registry for Kidney Diseases 1965–2015

\*Other systemic diseases, urinary tract obstruction, congenital diseases, and tubulointerstitial nephritis, among others

The incidence of RRT according to diagnosis appears as smoothed averages in Figure 2. Until the end of the 1990s, the incidence increased in almost all diagnostic groups, but thereafter the increase stopped or even declined.

Type 2 diabetes has been the leading cause of end-stage renal disease since 1999. Type 1 diabetes and glomerulonephritis rank as the second most common causes of end-stage renal disease. The incidence of RRT due to poly-

cystic kidney degeneration has slightly increased in recent years. The number of amyloidosis patients entering RRT has decreased continuously since 2000.

The group “other defined diagnosis” was in 2015 larger than earlier. Within this group, the most frequent ICD-10 diagnosis was N18.8 (other defined renal insufficiency), and this diagnosis had also increased the most.

Table 6. Number of RRT patients at 90 days from start of RRT according to type of treatment in healthcare districts and regions

Table 6 presents the number of RRT patients at 90 days from start of RRT in 2011–2015 according to type of treatment in healthcare districts and regions. Of the 2268 patients, only 17 (0.7%) had received a kidney graft (Tx), 27% were on continuous ambulatory or automated peritoneal dialysis (CAPD or APD), 4% were on home hemodialysis (home HD), and 68% were on either in-center hemodialysis (in-center HD) or hemodiafiltration (HDF).

Figure 3. Distribution of treatment modalities at 90 days from start of RRT in patients older than 20 years Finnish Registry for Kidney Diseases 2005–2015

Figure 4. Proportion of home dialysis and kidney transplantation patients of all RRT patients older than 20 years at 90 days from start of RRT Finnish Registry for Kidney Diseases 2011–2015

Figure 3 shows the distribution of RRT patients' treatment modalities at 90 days from start of RRT in 2005–2015 (n=5024). The combined proportion of home dialysis and kidney transplantation patients was similar in 2015 as in 2005, about 30%. The proportion of kidney transplantation patients was slightly larger in 2015 (2%) than earlier. The proportion of patients on continuous (CAPD) or automated peritoneal dialysis (APD) was smaller in 2015 than in earlier years. The proportion of patients on home hemodialysis (Home HD) has increased during the ten-year period. The

proportion of hemodiafiltration (HDF) is small (underreporting suspected), but has increased in recent years.

The combined proportion of home dialysis (CAPD, APD, and home HD) and kidney transplantation at 90 days from start of RRT was 32% in the entire country in 2011–2015 (Figure 4). The proportion varied significantly according to healthcare district (0–45%) and region (28–35%). The P-values shown in the Figure were adjusted for age and sex using binary logistic regression. For comparison, a similar analysis was presented in Report 2012 on page 24.

Figure 5. International comparison of incidence of RRT in 2014  
Finnish Registry for Kidney Diseases 2014

Figure 5 shows the incidence of RRT in 2014 in countries reporting to the ERA-EDTA Registry (Annual Report 2014, <http://www.era-edta-reg.org>) and in the United States, Canada, Australia, New Zealand, Japan, and Russia (The 2016 USRDS Annual Data Report Atlas, <http://www.usrds.org>). In 2014, the incidence of RRT in Finland was the second lowest among the Nordic countries. Relative to Finland, the incidence in Denmark was 55% higher, in Sweden 43% higher, in Norway 21% higher, and in Iceland 31% lower.

Table 7 presents the number of RRT patients and the prevalence of RRT on 31 December 2005–2015. In the entire country, the prevalence at the end of 2015 was 851 RRT patients per million inhabitants. On 31 December 2015, the prevalence was the highest in the southwestern and eastern regions and the lowest in the northern region. In the healthcare districts, the prevalence varied between 654 and 1174 patients per million inhabitants.

In the entire country, the prevalence has increased by 7% from 2010. The prevalence has increased in all regions, the most in the eastern region (13%) and the least in the southwestern region (4%). In the healthcare districts, the prevalence has increased the most during the past five years in Vaasa (20%). In two healthcare districts (Länsi-Pohja and Satakunta), the prevalence has decreased.

Figure 6. Standardized prevalence of RRT in regions  
Finnish Registry for Kidney Diseases 2005–2015

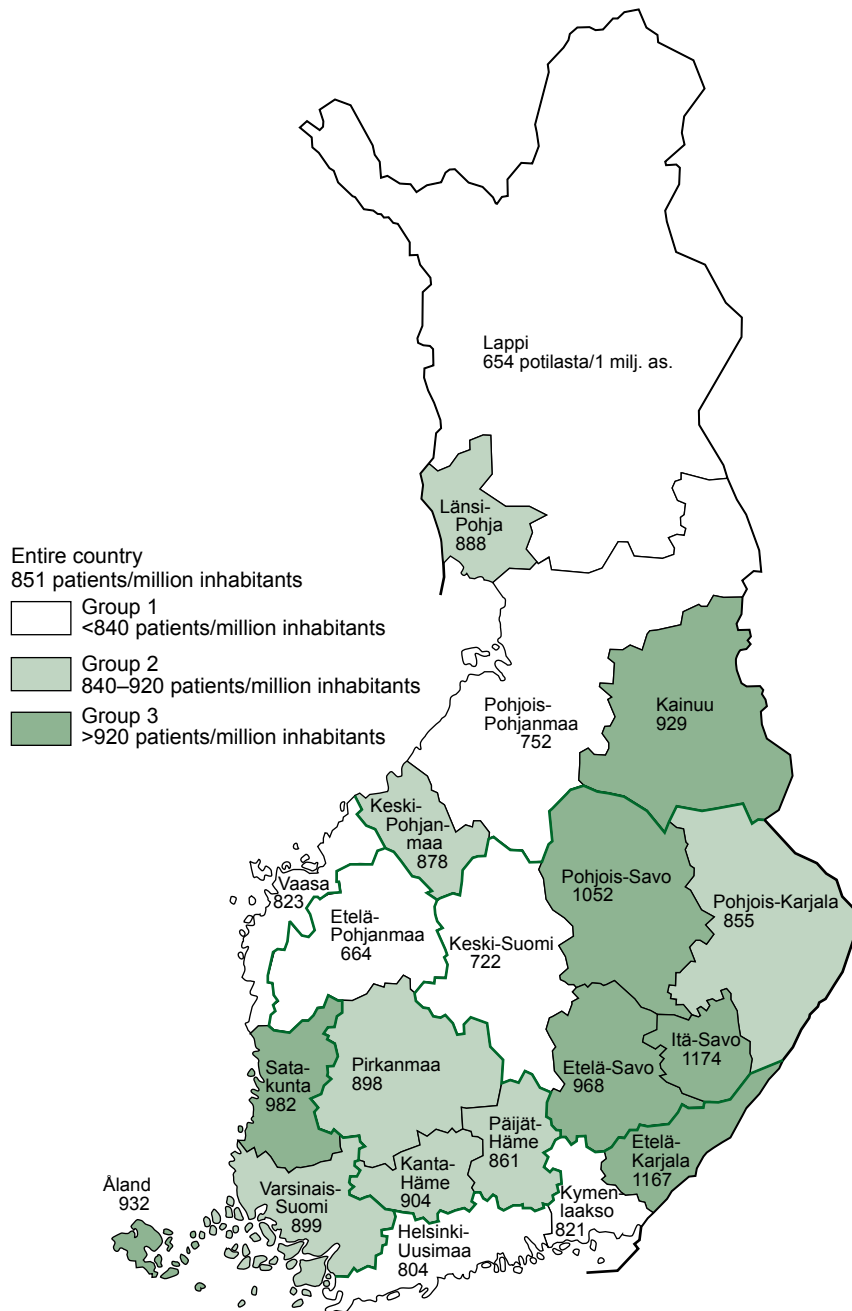

Table 8 shows the number of RRT patients and the prevalence of RRT on 31 December 2005–2015 according to age group and sex. The prevalence of RRT has increased by 18% since 2005. The prevalence has increased by 19% in the age group of 75 years and older, by 26% in the age group of 65–74-year-olds, and by 16% in the age group of 45–64-year-olds. In the younger age groups, the prevalence of RRT has decreased by 8–9% during the past ten years. The highest prevalence, observed among men aged 65–74 years at the end of 2015, was 2632 cases per million age-related inhabitants. At the end of 2015, the prevalence was 83% greater among men than women, and the sex difference was even more pronounced in the oldest age group, in which it was threefold as high in men.

Figure 6 shows the age- and sex-standardized prevalence rates for 2005–2015 using the Finnish general population on 31 December 2015 as the reference population. Population changes during this period have been taken into consideration. The standardized prevalence rates have increased slowly in recent years, and the differences between regions are small.

Figure 7. Prevalence of RRT on 31 December 2015  
Finnish Registry for Kidney Diseases 2015

The healthcare districts shown on the map are grouped according to the prevalence of RRT at the end of 2015 (Figure 7). The prevalence per million inhabitants was <840 in seven districts, 840–920 in seven districts, and >920 in seven districts. The borders of the regions are indicated with thick lines.

Figure 8. Prevalence of RRT at end of year according to type of treatment  
Finnish Registry for Kidney Diseases 1965–2015

Figure 8 displays the prevalence of RRT according to treatment type. The prevalence of kidney transplantation has shown a continuous increase, 10% during the past five years. The number of in-center hemodialysis patients has not increased in the past five years. The number of patients on peritoneal dialysis has remained virtually unchanged for

decades, but the proportion of automated peritoneal dialysis (APD) increased until 2005, while that of continuous ambulatory peritoneal dialysis (CAPD) decreased. Since 2005, the proportion of APD patients of all PD patients has been about 60%. The number of home hemodialysis patients has increased by 81% during the past five years.

Table 9 presents the prevalence of dialysis and kidney transplantation per million inhabitants in healthcare districts and regions in 2005–2015. The prevalence of dialysis has increased by 13% and that of kidney transplantation by 24% during the past ten years. During the past five years, the prevalence of dialysis has increased by 2%. At the end of 2015, the prevalence of dialysis varied between 212 and 476 per million inhabitants and that of kidney transplantation between 345 and 713 per million inhabitants. In regions, the prevalence of dialysis varied between 294 and 359 per million inhabitants and that of kidney transplantation between 485 and 556 per million inhabitants.

Table 10 presents the number of RRT patients according to type of treatment in healthcare districts and regions at the end of 2015. The proportion of peritoneal dialysis patients was the greatest in the healthcare district of Varsinais-Suomi, where 12% of all RRT patients were receiving either continuous ambulatory peritoneal dialysis (CAPD) or automated peritoneal dialysis (APD). The proportion of patients on home hemodialysis (home HD) was largest, 6%, in the healthcare district of Kymenlaakso. In six healthcare districts, there were no home HD patients. The proportion of kidney transplantation patients varied between 46% and

71% in the healthcare districts ( $P=0.029$  in age- and gender-adjusted analysis using binary logistic regression). The difference between regions was not significant ( $P=0.687$ ).

Of all RRT patients, 25% were on home dialysis (CAPD, APD, or home HD) at the end of 2015. The proportion of home dialysis was higher than 30% in five healthcare districts (Lappi, Varsinais-Suomi, Helsinki-Uusimaa, Kymenlaakso, and Päijät-Häme) and lower than 15% in three healthcare districts.

Figure 9. International comparison of prevalence of RRT on 31 December 2014  
Finnish Registry for Kidney Diseases 2014

Figure 9 displays the prevalence of RRT on 31 December 2014 in countries reporting to the ERA-EDTA Registry (Annual Report 2014, <http://www.era-edta-reg.org>) and in the United States, Canada, Australia, New Zealand, Japan, and Russia (The 2016 USRDS Annual Data Report Atlas, <http://www.usrds.org>). The prevalence rate in Finland was the fourth lowest internationally and the second lowest of the Nordic countries. Relative to Finland, the prevalence in Sweden was 14% higher, in Norway 10% higher, and in Denmark 8% higher. Figure 5 shows the international incidence rates.

Table 11 presents the number of patient-years according to diagnosis of kidney disease and type of treatment in 2005 and 2015. The number of patient-years indicates time spent by patients in RRT during the year. Overall, the number of patient-years has increased by 26% since 2005. The number of patient-years has increased by 25% in hemodialysis and by 29% in kidney transplantation. The number of patient-years in peritoneal dialysis has remained virtually unchanged.

Glomerulonephritis is the most common diagnosis among all RRT patients and among kidney transplantation patients; the proportion of patient-years due to glomerulonephritis was 22% in 2015. Type 1 diabetes is the

second most common diagnosis among all RRT patients and the most common diagnosis among peritoneal dialysis patients. The number of patient-years in patients with polycystic degeneration has increased by 45% during the last ten years. Polycystic degeneration is the second most common diagnosis of kidney transplantation patients. Type 2 diabetes is the fourth most common kidney disease diagnosis of all RRT patients and the most common among hemodialysis patients.

The proportion of patient-years due to amyloidosis has decreased by 48% since 2005. The proportion of undefined kidney disease has increased during the past decade, reaching 9.4% in 2015.

Figure 10. Net changes in type of treatment  
Finnish Registry for Kidney Diseases 2015

During 2015 altogether 519 new patients entered RRT (Figure 10), and seven patients returned to RRT. In all, 4572 patients were receiving RRT at the beginning of the year. Altogether 403 patients died and dialysis was discontinued for 21 patients because the patient's own kidney function resumed. Of those who died, 103 had a functioning kidney transplant, 36 were receiving peritoneal dialysis, and 205 were on hemodialysis. During 2015 RRT was discontinued for 60 uremic patients. At the end of 2015, the number of peritoneal dialysis patients was 3% smaller, the number of

hemodialysis patients 3% larger, and the number of kidney transplantation patients 2% larger than at the beginning of the year.

A total of 244 patients received a kidney transplant. Of these patients, 18 received a combined pancreas and kidney transplantation, and one a combined heart and kidney transplantation (source: Kidney Transplantation Unit, Helsinki University Central Hospital). Fifteen kidney transplants were received from living donors. Four kidney transplantation patients moved abroad (not shown in Figure 10).

Table 12. Mortality of RRT patients by region

Figure 11. Standardized mortality of RRT patients by region  
Finnish Registry for Kidney Diseases 2005–2015

Figure 12. Standardized mortality of RRT patients by region (patients who died within 90 days of start of RRT excluded)  
Finnish Registry for Kidney Diseases 2005–2015

Table 12 shows RRT patients' mortality in 2005–2015 according to region. The mortality of patients who had been on RRT for at least 90 days is presented separately. The average mortality in 2011–2015 was lower in the southern region than elsewhere.

Figures 11 and 12 show regional mortality as smoothed averages. The regional mortality rates for 2005–2015 have

been age- and sex-standardized using all patient-years in 2015 as the reference. Changes in age and sex distribution during this ten-year period have been taken into consideration. Patients who died within 90 days of start of RRT were excluded from Figure 12. During the period 2005–2015 the standardized mortality rate has declined in all regions.

At the end of 2015, dialysis and kidney transplantation patients were treated and followed up in 30 hospitals of 21 healthcare districts in five regions (Table 13). In the first part of this report, the healthcare district of the patient is determined according to place of residence. However, in

the analysis of treatment quality on pages 26–42, healthcare district of the patient is determined according to treating hospital. In the entire country, 98% of patients lived in the same healthcare district where they were treated.

Figure 13. Nephrological follow-up before start of RRT in patients older than 20 years according to year of start of RRT  
Finnish Registry for Kidney Diseases 2011–2015

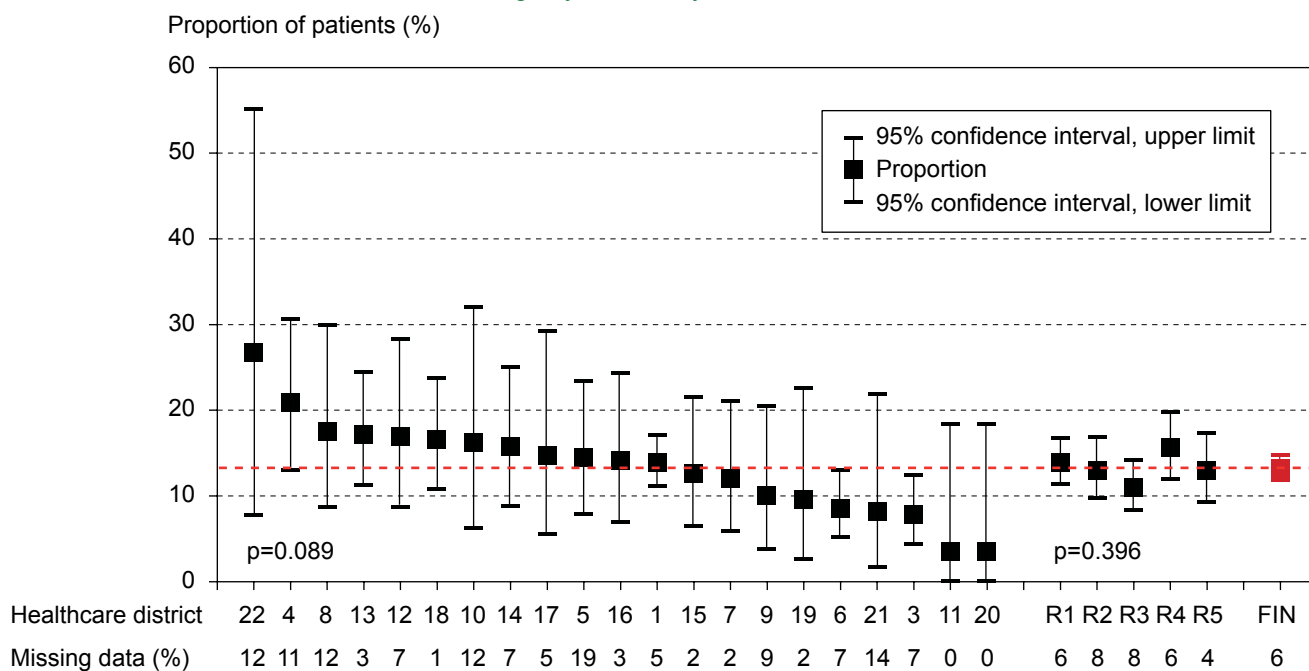

Figure 14. Proportion of patients older than 20 years with nephrological follow-up shorter than 7 days before start of RRT  
Finnish Registry for Kidney Diseases 2011–2015

The Finnish Registry for Kidney Diseases has since 2011 collected information on when a patient first was followed up by a nephrologist. During 2011–2015 altogether 2323 patients aged 20 years or older entered RRT. More than half had been under nephrological follow-up for more than two years, but 13 has been followed up for less than seven days before start of RRT (Figure 13).

The proportion of patients followed up by a nephrologist

for less than seven days before start of RRT varied from 4% to 21% in healthcare districts ( $P=0.089$ ) and from 11% to 16% in regions ( $P=0.396$ ) (Figure 14). The proportion did not differ between sexes ( $P=0.267$ ).

All P-values on pages 27–42 were adjusted for age and sex by using binary logistic regression in which treatment target was the binary outcome and healthcare district (or region), age, and sex were explanatory variables.

Figure 15. Nephrological follow-up before start of RRT of patients older than 20 years according to age group and sex  
Finnish Registry for Kidney Diseases 2011–2015

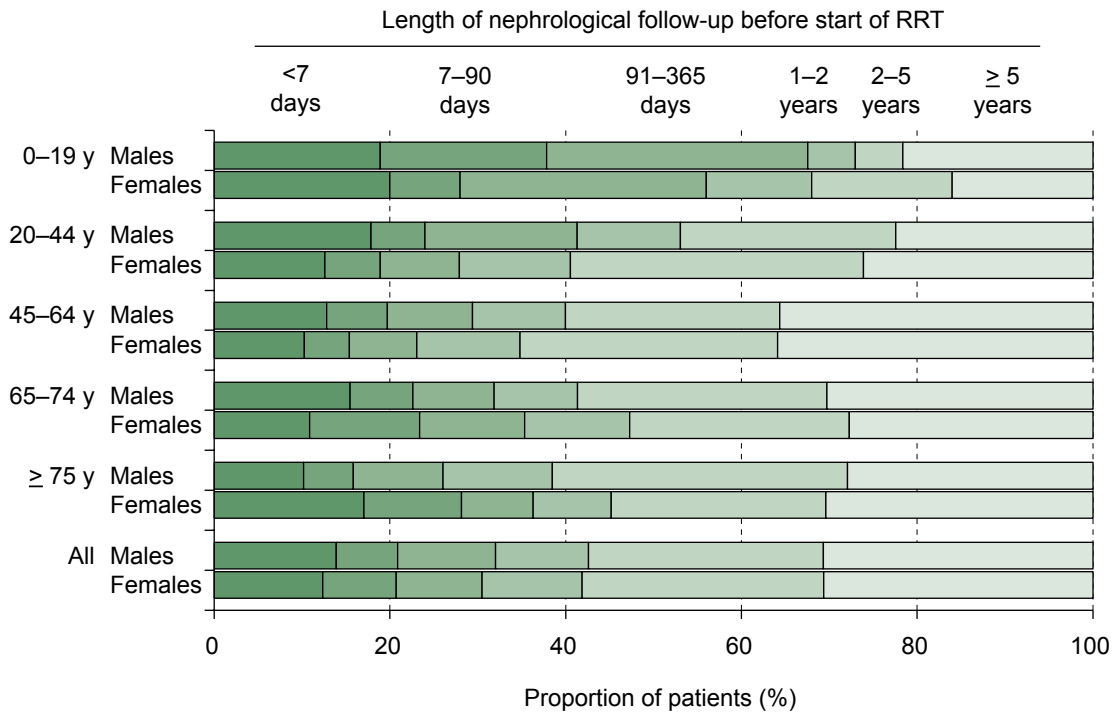

Figure 15 displays according to age group and sex the length of nephrological follow-up before start of RRT in patients who entered RRT in 2011–2015. The median follow-up was 2.8 years, and significant differences were observed between age groups ( $P=0.001$ ), but not between sexes ( $P=0.966$ ).

Figure 16. Hemoglobin distribution of dialysis patients older than 20 years at end of year  
Finnish Registry for Kidney Diseases 2005–2015

Figure 17. Proportion of dialysis patients older than 20 years with hemoglobin concentration  $\geq 100$  g/l in healthcare districts and regions  
Finnish Registry for Kidney Diseases 2015

Several guidelines exist regarding the target for blood hemoglobin concentration in dialysis patients: European Best Practice Guidelines (EPBG) and the guidelines of the Kidney Disease Outcome Quality Initiative (KDOQI) and the Kidney Disease Global Outcomes (KDIGO). KDIGO published new guidelines on renal anemia in 2012, according to which erythropoietin-stimulating agents (ESAs) should be used to keep dialysis patients' hemoglobin in the range of 100–115 g/l.

The renal registries in the UK and Sweden have in their reports used target hemoglobin levels of either 100–120 g/l or  $\geq 100$  g/l. For sake of comparison, we have chosen the same cut-offs.

The distribution of dialysis patients' hemoglobin concen-

tration has changed considerably during 2004–2014 (Figure 16). The proportion of patients with a hemoglobin concentration lower than 100 g/l has increased and was 15% at the end of 2015. The proportion of patients with a hemoglobin concentration of 120 g/l or higher has decreased to less than half and was 23% in 2015. Figures 16 and 17 include all hemodialysis patients, also those who did not use ESAs.

In Figure 17, the hemoglobin target is 100 g/l or higher. At the end of 2015, the proportion of dialysis patients reaching this target was 85% and varied from 75% to 96% in the healthcare districts ( $P=0.384$ ) and from 80% to 87% in the regions ( $P=0.178$ ). No significant difference was present in the proportions of men and women with a hemoglobin concentration of 100 g/l or higher.

Figure 18. Distribution of serum phosphorus among dialysis patients older than 20 years at end of year Finnish Registry for Kidney Diseases 2005–2015

Figure 19. Proportion of dialysis patients older than 20 years with serum phosphorus <1.8 mmol/l in healthcare districts and regions Finnish Registry for Kidney Diseases 2015

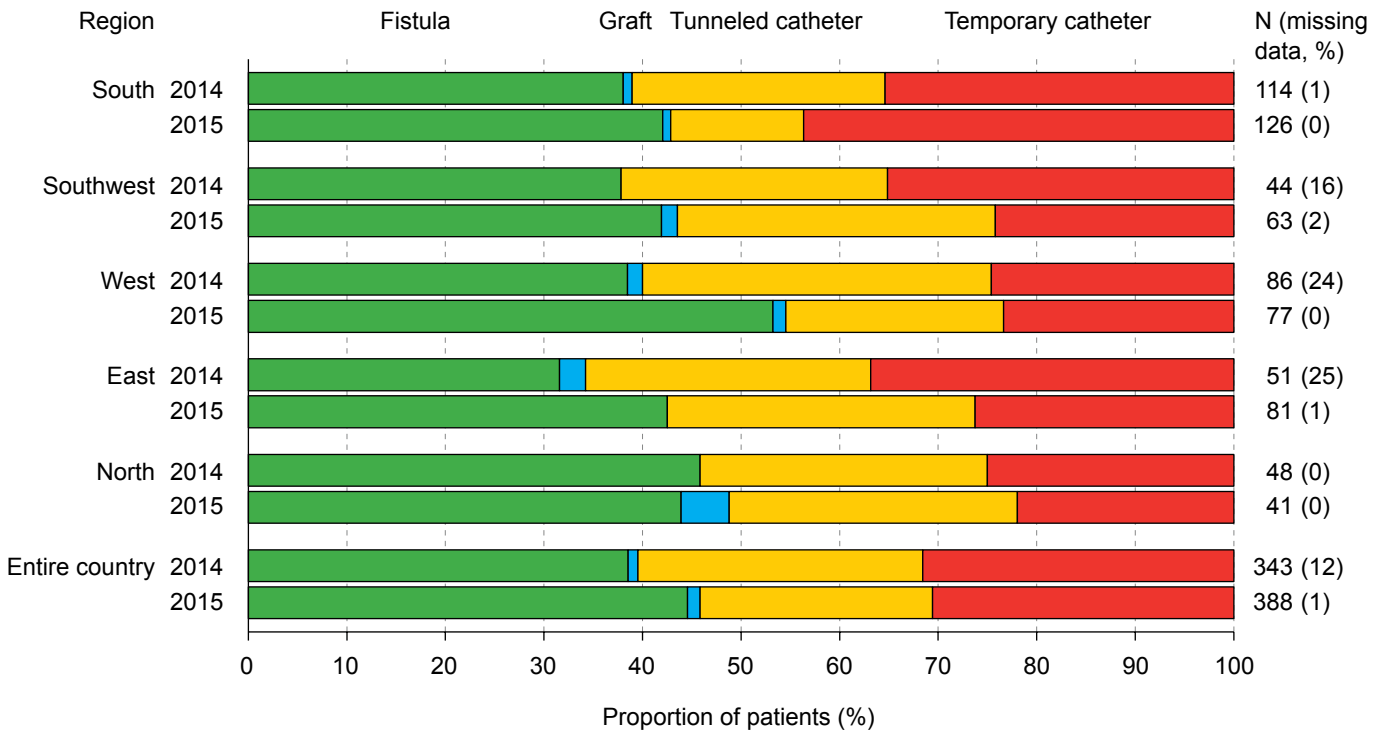

Hyperphosphatemia among patients with kidney disease is associated with vascular calcification and increased mortality. The guideline of the Kidney Disease Global Outcomes (KDIGO) suggests that elevated serum phosphorus of dialysis patients should be lowered towards the normal range with diet, intensified dialysis treatment, and phosphate binders if needed.

At the end of 2015, 69% of hemodialysis and peritoneal dialysis patients had concentrations of serum phosphorus lower than 1.8 mmol/l; this proportion has remained virtu-

ally unchanged during the past ten years (Figure 18). Only 2% of dialysis patients had an excessively low concentration of serum phosphorus (<0.8 mmol/l).

The proportion of patients reaching the treatment target (serum phosphorus <1.8 mmol/l) varied between 53% and 88% in the healthcare districts (P=0.003) and between 59% and 75% in the regions (P<0.001) (Figure 19). No significant difference was present in the proportions of men and women reaching the treatment target.

Figure 20. Vascular access of new hemodialysis patients older than 20 years by region  
Finnish Registry for Kidney Diseases 2014–2015

The Finnish Registry for Kidney Diseases has since 2014 collected data on vascular access of patients entering hemodialysis as first type of RRT. The recommended type of vascular access is an arteriovenous fistula or graft. A temporary (non-cuffed) central venous catheter is recommended only when dialysis is started acutely and other types of vascular access are not possible.

In 2015, 46% of patients older than 20 years who entered hemodialysis had an arteriovenous fistula or graft and the proportion varied 45–55% in regions ( $P=0.489$ ) (Figure 20). Of the patients entering hemodialysis in the entire country, 31% had a temporary catheter and this proportion varied from 22% to 44% in regions ( $P=0.002$ ).

Figure 21. Vascular access of hemodialysis patients older than 20 years at end of year  
Finnish Registry for Kidney Diseases 2005–2015

Patients who had been on RRT less than one year were excluded.

Figure 22. Proportion of hemodialysis patients older than 20 years with a fistula or graft in healthcare districts and regions  
Finnish Registry for Kidney Diseases 2015

Patients who had been on RRT less than one year were excluded.

Vascular access is one of the most important quality measures in hemodialysis. Use of a central venous catheter is associated with complications, and the goal is that hemodialysis patients have an arteriovenous fistula or graft. Of hemodialysis patients aged 20 years or older who had been on RRT for at least one year, the proportion with a fistula or graft was the largest, 90%, in 2006, after which it decreased and has been 85% since 2014 (Figure 21).

At the end of 2015, the proportion of patients with a fistula or graft varied between 69% and 100% in healthcare districts (excluding healthcare district 22, in which only 3 patients fulfilled inclusion criteria) ( $P=0.007$ ) and between 80% and 87% in regions ( $P<0.001$ ) (Figure 22). At the end of 2015, female hemodialysis patients less frequently than male patients had a fistula or graft (80% vs. 88%,  $P=0.001$ ).

Figure 23. Sufficiency of dialysis time among hemodialysis patients aged 20–74 years  
Finnish Registry for Kidney Diseases 2005–2015

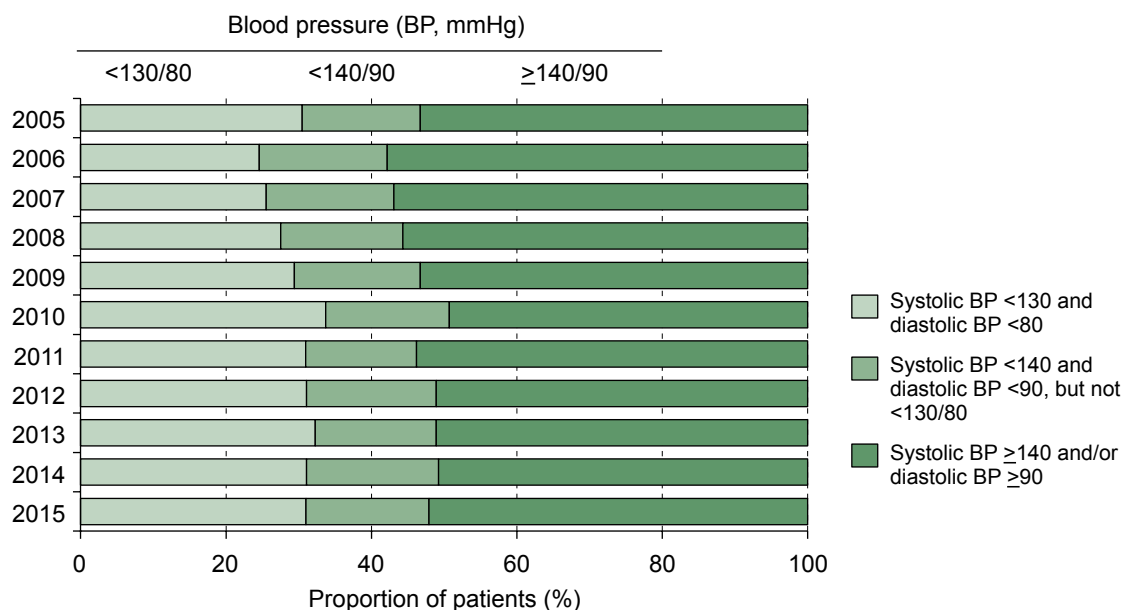

Figure 24. Proportion of hemodialysis patients aged 20–74 years with sufficient dialysis time in healthcare districts and regions  
Finnish Registry for Kidney Diseases 2015

According to the European Best Practice Guidelines (EBPG), hemodialysis should be performed at least three times and for at least 12 hours a week if there is no significant residual kidney function. According to this definition, 91% of 20–74-year-old in-center hemodialysis patients received sufficient hemodialysis time at the end of 2015 (Figure 23). The proportion has remained virtually unchanged during recent years. At the end of 2015, the proportion varied between 76%

and 100% in healthcare districts (excluding healthcare district 22, in which only 2 patients fulfilled inclusion criteria) ( $P=0.068$ ) and between 85% and 94% in regions ( $P=0.027$ ) (Figure 24). After adjustment for age and sex, the difference between healthcare districts was not significant ( $P=0.051$ ). At the end of 2014, female hemodialysis patients less frequently than males had sufficient dialysis time (87% vs. 93%,  $P=0.014$ ).

Figure 25. Distribution of predialytic blood pressure among hemodialysis patients older than 20 years  
Finnish Registry for Kidney Diseases 2005–2015

Patients who had been on RRT less than one year and home hemodialysis patients were excluded.

Figure 26. Proportion of hemodialysis patients older than 20 years with predialytic blood pressure <140/90 mmHg in healthcare districts and regions  
Finnish Registry for Kidney Diseases 2015

Patients who had been on RRT less than one year and home hemodialysis patients were excluded (n=1084).

According to the guidelines of the Kidney Disease Outcome Quality Initiative (KDOQI), hemodialysis patients' target for predialytic blood pressure is lower than 140/90 mmHg. At the end of 2015, 48% of hemodialysis patients reached this target (Figure 25). The proportion of patients reaching the

target varied between 15% and 100% in healthcare districts (P=0.225) and between 45% and 52% in regions (P=0.639) (Figure 26). There was no significant difference in proportions of males and females reaching the target blood pressure.

Figure 27. Number of PD peritonitis patients older than 20 years according to annual number of episodes of peritonitis  
Finnish Registry for Kidney Diseases 2005–2015

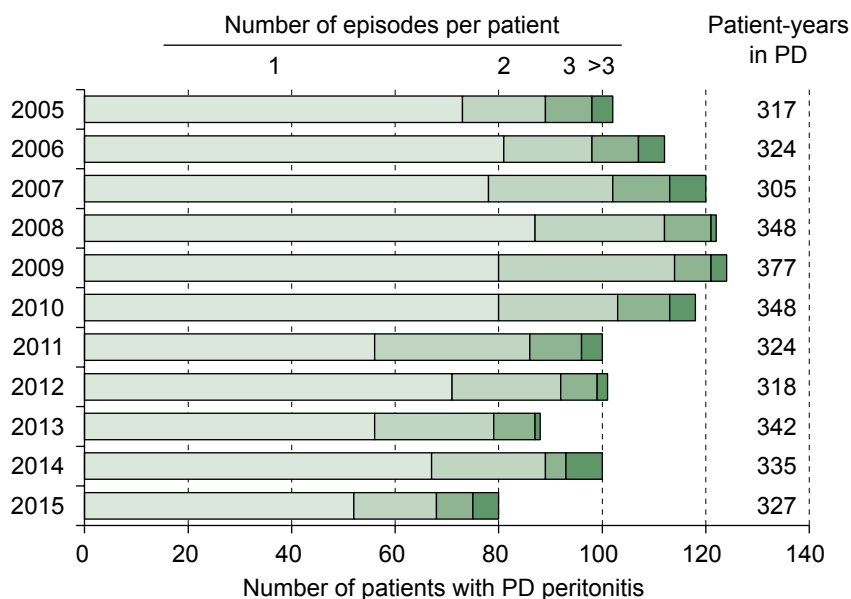

Figure 28. Incidence density of peritonitis among PD patients older than 20 years in regions.  
Finnish Registry for Kidney Diseases 2005–2015

Figure 27 presents the number of peritoneal dialysis (PD) patients who had had at least one episode of peritonitis per calendar year during 2005–2015. Of PD patients with peritonitis in 2015, 35% had had more than one episode.

Figure 28 shows PD patients' incidence density of peritonitis, i.e. number of peritonitis episodes per 1000 patient-years in PD. If the patient had more than three epi-

sodes of peritonitis during one calendar year, only the first three episodes were considered. In the entire country, the incidence density of PD peritonitis was 420 per 1000 patient-years in 2011–2015, and this was 15% less than in 2005–2010 ( $P < 0.001$ ). The incidence density of PD peritonitis has declined in most regions.

Figure 29. Incidence density of peritonitis among PD patients according to age group and sex  
Finnish Registry for Kidney Diseases 2011–2015

Figure 30. Incidence density of peritonitis among PD patients older than 20 years according to age group and diabetes status  
Finnish Registry for Kidney Diseases 2011–2015

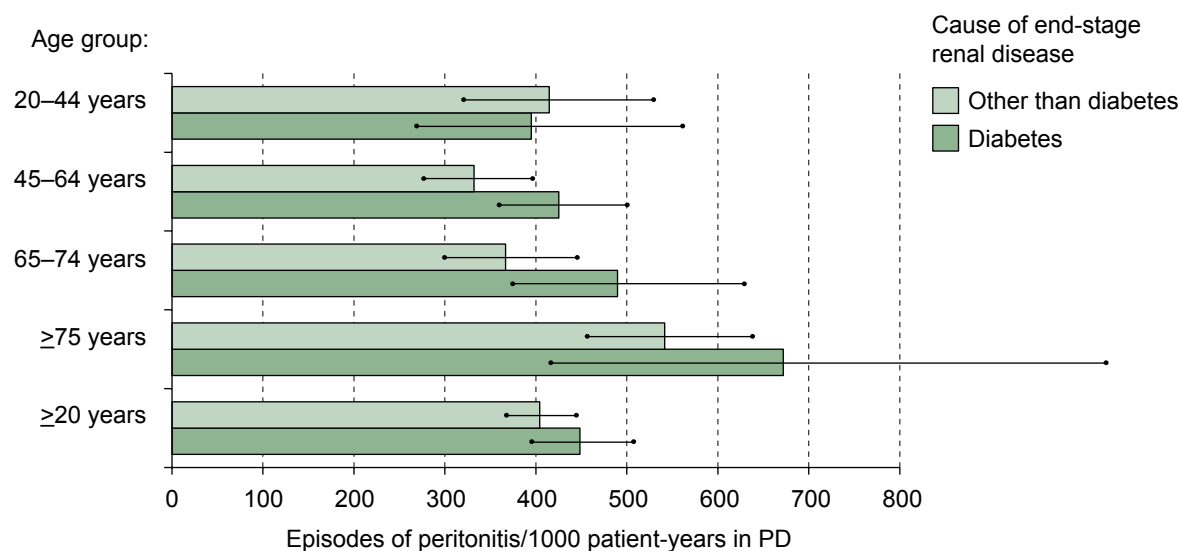

Figure 29 shows peritoneal dialysis (PD) patients' incidence density of peritonitis according to age group and sex in 2011–2015. During this time there were 1684 patient-years in PD and 712 episodes of peritonitis. If the patient had more than three episodes of peritonitis during one calendar year, only the first three episodes were considered when calculating the incidence density. Among patients younger than 20 years, 21 episodes of peritonitis were observed in 37 patient-years, and due to the small number the confidence intervals of the incidence density are wide. Patients older than 75 years had 41% higher risk of peritonitis than

younger patients ( $P < 0.001$ ), and males had 38% higher risk than females ( $P < 0.001$ ).

PD patients aged 20 years or older with diabetes as the cause of end-stage renal disease had higher incidence density of peritonitis than those with other causes of end-stage renal disease ( $P < 0.001$ ), and the difference is emphasized among patients older than 45 years (Figure 30). The data of patients younger than 20 years are not shown, as no one in this age group had diabetes as the cause of end-stage renal disease.

Figure 31. Time to waitlisting for kidney transplantation of new RRT patients older than 20 years  
Finnish Registry for Kidney Diseases 2005–2015

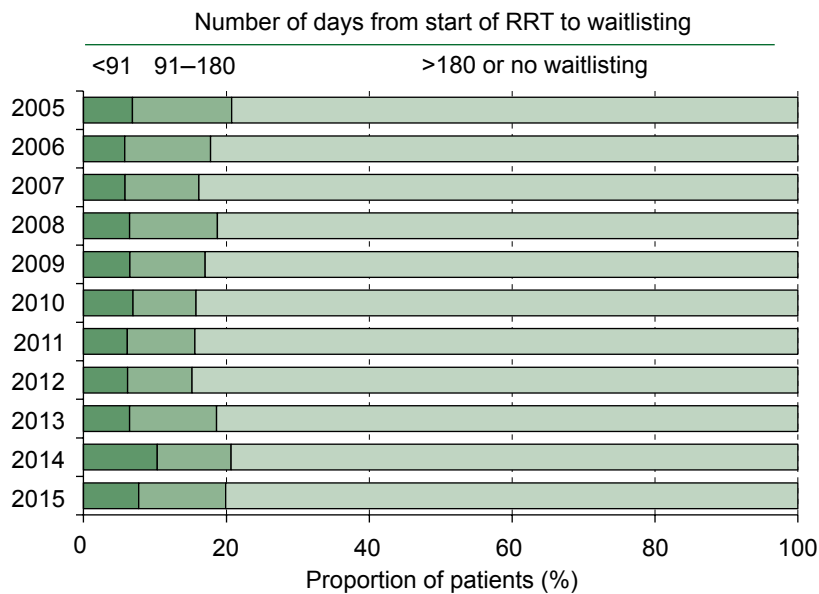

Figure 32. Time to waitlisting for kidney transplantation by age group of new RRT patients older than 20 years  
Finnish Registry for Kidney Diseases 2005–2015

In 2005–2015, altogether 5143 patients older than 20 years entered RRT. Of these, four received a kidney transplant without preceding dialysis treatment. Patients who had died within 180 days from start of RRT (N=280) were excluded from the analyses in Figures 31 and 32. Because data on waitlisting for transplantation were not available after 31 December 2015, patients who entered RRT after 1 July 2015 were excluded to keep the follow-up data complete. The analysis included a total of 4631 patients.

Figure 31 shows the time from start of RRT until waitlisting for kidney transplantation. In 2015, 8% of patients who

entered RRT were waitlisted within 90 days and 20% within 180 days from start of RRT. In 2014 and 2015, a somewhat larger proportion, 20%, than in earlier years was waitlisted within 180 days from start of RRT. Information on waitlisting was provided by the Registry for the Follow-up of Kidney Transplantation Patients at Helsinki University Central Hospital.

Figure 32 displays according to age group the time from start of RRT to waitlisting for kidney transplantation of patients who entered RRT in 2005–2015.

Figure 33. Proportion of new RRT patients waitlisted for kidney transplantation within 91 days from start of RRT in healthcare districts  
Finnish Registry for Kidney Diseases 2011–2015

Figure 34. Proportion of new RRT patients waitlisted for kidney transplantation within 181 days from start of RRT in healthcare districts  
Finnish Registry for Kidney Diseases 2011–2015

Figures 33 and 34 show the proportions of patients entering RRT in 2011–2015 who had been waitlisted for kidney transplantation within 90 and 180 days from start of RRT. Patients who had died within 180 days from start of RRT and those who entered RRT after 1 July 2015 were excluded from the analyses.

In the entire country, 7% of patients had been waitlisted within 90 days from start of RRT (Figure 33), and this proportion showed a range of 1–24% in healthcare districts ( $P < 0.001$ ) and 4–11% in regions ( $P = 0.003$ ). From start of

RRT, 10% of female and 6% of male patients were waitlisted within 90 days ( $P = 0.015$ ).

Of the patients, 18% had been waitlisted within 180 days from start of RRT (Figure 34). This proportion ranged from 11% to 30% in healthcare districts ( $P = 0.077$ ) and from 13% to 22% in regions ( $P = 0.247$ ). Within 180 days from start of RRT, 22% of women and 16% of men were waitlisted for kidney transplantation ( $P = 0.002$ ).

Number of kidney transplantations and incidence density of kidney transplantation

Figure 35. Standardized incidence density of kidney transplantation  
among dialysis patients  
Finnish Registry for Kidney Diseases 2005–2015

Table 14 presents the number of kidney transplantations performed on patients aged 20 years or older and dialysis patients' incidence density of kidney transplantation in regions in 2005–2015. In 2011–2015, dialysis patients' incidence density of kidney transplantation varied regionally in the range of 99–119 kidney transplantations per 1000 patient-years in dialysis.

Figure 35 shows regional incidence density of kidney transplantation as smoothed averages. The regional inci-

dence densities for 2005–2015 have been age- and sex-standardized using all dialysis patients' patient-years in 2015 as the reference. Changes in age and sex distribution during this ten-year period have been taken into account. The annual numbers of kidney transplantation were considerably larger in 2014 and 2015 than in earlier years. In recent years, the standardized incidence density of kidney transplantation has been similar among dialysis patients in all regions.

Figure 36. Incidence density of kidney transplantation among dialysis patients according to age group and sex  
Finnish Registry for Kidney Diseases 2005–2015

Figure 37. Incidence density of kidney transplantation among dialysis patients according to age group and time period  
Finnish Registry for Kidney Diseases 2005–2015

In 2005–2015, altogether 2081 kidney transplantations were performed and there were 18 731 patient-years on dialysis in the entire country. Only 13 kidney transplantations were performed without preceding dialysis treatment. Figures 36 and 37 present dialysis patients' incidence density of kidney transplantation, i.e. the number of kidney transplantations per 1000 patient-years in dialysis.

The incidence density of kidney transplantation is smaller in the older age groups, but there is no difference between the sexes (Figure 36). On average 178 kidney transplan-

tations were performed annually in 2005–2013, and in 2014–2015 the average was 238 kidney transplantations per year, which is 34% more than earlier. Dialysis patients' incidence density of kidney transplantation was 23% larger in 2014–2015 than in 2005–2013 (Figure 37). Incidence density increased by 30% among 45–64-year-olds and by 73% among those older than 65 years. Among dialysis patients younger than 45 years, incidence density of kidney transplantation did not increase significantly.

Figure 40. Distribution of serum LDL cholesterol among kidney transplantation patients older than 20 years Finnish Registry for Kidney Diseases 2005–2015

Figure 41. Proportion of kidney transplantation patients older than 20 years with serum LDL cholesterol <2.6 mmol/l in healthcare districts and regions Finnish Registry for Kidney Diseases 2015

According to the KDIGO and KDOQI guidelines, kidney transplantation patients' concentration of serum low-density lipoprotein (LDL) cholesterol should be less than 2.6 mmol/l. In 2015, 64% of kidney transplantation patients reached this target (Figure 40).

The proportion of kidney transplantation patients reaching the treatment target for LDL cholesterol varied between 22% and 76% in healthcare districts ( $P<0.001$ ) and between 58% and 70% in regions ( $P<0.001$ ) (Figure 41).

Males reached the target more frequently than females (66% vs. 60%,  $P=0.008$ ).

The concentration of LDL cholesterol was calculated using the Friedewald formula based on serum concentrations of total cholesterol, high-density lipoprotein (HDL) cholesterol, and triglycerides. Because of the restrictions of the Friedewald formula, patients with a concentration of triglycerides higher than 4.5 mmol/l were excluded (1% of patients).
